Project Implementation Review

FACE RECOGNITION ATTENDANCE SYSTEM USING AI

The project offers an Adaptive Air Quality Prediction System based on a hybrid machine learning technique, incorporating Support Vector Machine (SVM), Decision Tree, and Linear Regression models. The system seeks to improve air quality forecasting precision through the use of several predictive algorithms to examine pollutant concentrations and environmental conditions. Through the combination of these models, the system adjusts to different patterns of data, enhancing prediction reliability. The method guarantees scalability and resilience, making it appropriate for varied urban and industrial settings. Secure data handling processes mitigate privacy issues while guaranteeing ethical compliance. The system offers real-time updates, minimizing errors and supporting proactive air pollution control. Comparative analysis with conventional methods indicates the efficiency of the hybrid model. Future development will investigate deep learning integration and real-time sensor-based enhancements, furthering the development of AI based air quality forecasting solutions.
